Throughout Materials Explorers™ you’ve seen the importance of materials selection in designing a product. You’ve also learned about the scientific method, a logical or systematic approach to problem solving. Now, you’ll be able to apply that knowledge to conceptualize and design your very own product.

In this module students will be able to:

- Evaluate a solution to a complex, real-world problem that can be solved through materials applications
- Analyze and evaluate different material properties
- Develop a practical solution to a complex, real-world problem
- Present the solution through a poster presentation and optional prototype
From airplanes, to smartphones, to medical advancements: the entire history of our world has been shaped by scientists and engineers who identified a problem and worked towards a solution. Sometimes it was by challenging what was considered possible but, many times, it was by looking at a commonplace object and figuring out how it could be improved.

When designing a new product or part, scientists must also select the most suitable material. This is done by carefully considering the qualities their product will need and the conditions it has to endure before selecting the material that best meets those needs. Here’s a practical example: if you were asked to design a new type of baseball bat, what qualities would be most important to your final product? Cost would certainly be an important factor to you since it’s also important to your customers. Weight would also matter because players don’t want a bat that is too heavy to swing comfortably. The bat would also need to be durable enough to withstand the impact of a baseball (often several thousand Newtons of force) yet malleable enough for your machines to easily produce their iconic shape. Finally, you might want a bat that resists corrosion despite years of being stored in field houses or storage sheds.

With all these requirements, it’s easy to see why aluminum baseball bats are almost as popular as the traditional wood design. Aluminum is malleable, durable, lightweight, corrosion resistant, and cost effective—meeting all the requirements identified above. However, innovation doesn’t stop just because a new product is created: there’s always the chance to improve through another generation of designs and products.

Although aluminum and wood are very different from one another, both have properties that make excellent baseball bats. What are some important qualities to consider when producing a bat?
Capstone Project

You can also make the world a better place by identifying opportunities for improvement around you and proposing either a “next generation” design or something radically new. Stumped for ideas? Try asking classmates, friends or family about something they use frequently that causes them frustration. Or, try looking around at your school or community for situations that could be improved by a new or different application of materials. Then, think about what kinds of materials you would need in order to address these problems.

Problem:

Look around your home, school or greater community: there are likely many opportunities for improvement through a closer consideration of material selection and product design. You have the opportunity to make those improvements by either designing a completely new product or by improving a preexisting design and by selecting the best materials for creating your product.

Task:

1. Think about your home, school, neighborhood or even the world. Identify a problem that can be solved by constructing something original or by designing a radical improvement to a current product. If you are struggling to think of an idea, conduct a needs assessment by questioning your peers, family members, teachers or neighbors. Keep in mind that sometimes the day-to-day products that we take for granted can also benefit from a redesign.

2. Consider the way your design will be used and how this will influence it. Review the following list of properties and determine which three would be most important when selecting materials for your creation. Keep in mind, some parts of your design may have different requirements. If so, you must identify the three most important properties for each part or component.

- Appearance
- Conductivity
- Corrosion resistance
- Cost
- Density
- Formability
- Melting point
- Strength
- Toughness

Definition

Newtons
The International System of Units (SI) unit of force.
3. After selecting the three most important properties for your product, research which material(s) best fit those properties.

4. Create a poster to present your design concept, highlighting the materials used for your design and the properties that made you select them. Your poster must meet all of the requirements listed below.

5. Present your design to your class.

Requirements:

Develop a poster that outlines the following:

- The problem that is solved by constructing your item.
- The three essential properties that guided your material selection.
  *Note:* If the essential properties vary by component, list three essential properties for each part of your design.
- The materials selected and the reason you selected them.
- A sketch of your proposed product including a scale and labels of the material(s) being used.

Questions

1. Material selection is an important step in designing products. Address each of the following material selection considerations with regards to your project: cost, reliability, ease of joining materials, ease of fabrication, mechanical properties, and electrical properties.

2. Materials belong to different “classes” or categories such as metals, ceramics, foams, polymers, composites, and elastomers. For each of the materials used in your product design, research and identify the class of materials to which it belongs.

3. When deciding which materials are appropriate for a specific task, material scientists often reference “materials selection charts.” These charts map out the properties of different classes of materials and help scientists easily compare materials to one another.
   i. Research a materials selection chart that uses any one of the three material properties identified as “essential” in your poster presentation (for example, you may wish to search a materials selection chart showing density and strength, or one showing strength and cost).
   ii. Which class of materials performs best according to the chart?
   iii. Is it the same class of material as the one you initially selected for your design? If not, would you change your design now? Explain why, or why not.
The “Materials That Move Us” curriculum was developed through generous support from the Arconic Foundation.

Materials Explorers™ is a STEM educational outreach initiative of The Minerals, Metals & Materials Society (TMS). TMS is non-profit, international professional society with a mission to promote the global science and engineering professions concerned with minerals, metals, and materials.
